This example is adapted from a real production application, but with details disguised to protect confidentiality.

You are a famous researcher in the City of Peacetopia. The people of Peacetopia have a common characteristic: they are afraid of birds. To save them, you have **to build an algorithm that will detect any bird flying over Peacetopia** and alert the population.

The City Council gives you a dataset of 10,000,000 images of the sky above Peacetopia, taken from the city's security cameras. They are labelled:

• y = 0: There is no bird on the image

y = 1: There is a bird on the image
 Your goal is to build an algorithm able to classify new images taken by security cameras from Peacetopia.

There are a lot of decisions to make:

What is the evaluation metric?

How do you structure your data into train/dev/test sets?

Metric of success

The City Council tells you the following that they want an algorithm that

Has high accuracy
 Runs quickly and takes only a short time to classify a new image.

Can fit in a small amount of memory, so that it can run in a small processor that the city will attach to many different security cameras.

97%

Test Accuracy

optimizing metric.

want to do well on all three.

Which of these do you think is the best choice?

two different algorithms, and will slow down the speed with which your team can iterate.

True/False?

True

正确

False

Note: Having three evaluation metrics makes it harder for you to quickly choose between

After further discussions, the city narrows down its criteria to:

• "We need an algorithm that can let us know a bird is flying over Peacetopia as accurately as possible."

"We want the trained model to take no more than 10sec to classify a new image."
 "We want the model to fit in 10MB of memory."
 If you had the three following models, which one would you choose?
 Test Accuracy
 Runtime
 Memory size

1 sec

Runtime

3MB

Memory size

99% 13 sec 9MB

Test Accuracy Runtime Memory size
97% 3 sec 2MB

Test Accuracy Runtime Memory size 98% 9 sec 9MB

正确
Correct! As soon as the runtime is less than 10 seconds you're good. So, you may simply maximize the test accuracy after you made sure the runtime is <10sec.

Based on the city's requests, which of the following would you say is true?

Accuracy is an optimizing metric; running time and memory size are a satisficing metrics.

Accuracy, running time and memory size are all satisficing metrics because you have to do sufficiently well on all three for your system to be acceptable.

Structuring your data

Before implementing your algorithm, you need to split your data into train/dev/test sets.

After setting up your train/dev/test sets, the City Council comes across another 1,000,000 images, called the "citizens' data". Apparently the citizens of Peacetopia are so scared of birds that they volunteered to take pictures of the sky and label them, thus contributing

these additional 1,000,000 images. These images are different from the distribution of

images the City Council had originally given you, but you think it could help your

You should not add the citizens' data to the training set, because this will cause the

training and dev/test set distributions to become different, thus hurting dev and test set

Accuracy is a satisficing metric; running time and memory size are an

False

False

Adding this data to the training set will change the training set distribution.
However, it is not a problem to have different training and dev distribution. On the contrary, it would be very problematic to have different dev and test set distributions.

One member of the City Council knows a little about machine learning, and thinks you

the rest of the data (similar to the New York City/Detroit housing prices

The 1,000,000 citizens' data images do not have a consistent x-->y mapping as

should add the 1,000,000 citizens' data images to the test set. You object because:

正确

This would cause the dev and test set distributions to become different. This is a bad idea because you're not aiming where you want to hit.

正确

You train a system, and its errors are as follows (error = 100%-Accuracy):

network so as to drive down the 4.0% training error. Do you agree?

No, because there is insufficient information to tell.

Normal person #1 (not a bird watching expert)

Normal person #2 (not a bird watching expert)

error, how would you define "human-level performance"?

0.75% (average of all four numbers above)

Which of the following statements do you agree with?

0.3% (accuracy of expert #1)

0.4% (average of 0.3 and 0.5)

0.0% (because it is impossible to do better than this)

This suggests that one good avenue for improving performance is to train a bigger

Yes, because having 4.0% training error shows you have high bias.

Yes, because this shows your bias is higher than your variance.

No, because this shows your variance is higher than your bias.

You ask a few people to label the dataset so as to find out what is human-level performance. You find the following levels of accuracy:

Bird watching expert #1

0.3% error

Bird watching expert #2

0.5% error

If your goal is to have "human-level performance" be a proxy (or estimate) for Bayes

A learning algorithm's performance can never be better than human-level performance nor better than Bayes error.

A learning algorithm's performance can be better than human-level performance and better than Bayes error.

You find that a team of ornithologists debating and discussing an image gets an even

Based on the evidence you have, which two of the following four options seem the most

 10_{\circ} better 0.1% performance, so you define that as "human-level performance." After

working further on your algorithm, you end up with the following:

Human-level performance

promising to try? (Check two options.)

Try increasing regularization.

Try decreasing regularization.

Get a bigger training set to reduce variance.

Train a bigger model to try to do better on the training set.

You also evaluate your model on the test set, and find the following:

Human-level performance

You have underfit to the dev set.

You should get a bigger test set.

You should try to get a bigger dev set.

After working on this project for a year, you finally achieve:

Human-level performance

What can you conclude? (Check all that apply.)

implies Bayes error is ≤ 0.05

iterate.

未选择的是正确的

The City Council thinks that having more Cats in the city would help scare off birds. They are so happy with your work on the Bird detector that they also hire you to build a Cat detector. (Wow Cat detectors are just incredibly useful aren't they.) Because of years of working on Cat detectors, you have such a huge dataset of 100,000,000 cat images that

training on this data takes about two weeks. Which of the statements do you agree with?

Needing two weeks to train will limit the speed at which you can iterate.

Having built a good Bird detector, you should be able to take the same model and hyperparameters and just apply it to the Cat dataset, so there is no need to

Buying faster computers could speed up your teams' iteration speed and thus your team's productivity.

正確

If 100,000,000 examples is enough to build a good enough Cat detector, you might be better of training with just 10,000,000 examples to gain a ≈10x improvement in how quickly you can run experiments, even if each model performs a bit worse because it's trained on less data.
